

TEXING 2-CELLS IN DERIVATORS

IAN COLEY

As of the writing of this document, there does not seem a unified way of TEXing commutative diagrams which include 2-cells. All seem to use the `xymatrix` package, but the implementation differs. To compile the TEX to follow, the reader should include

```
\usepackage[all, 2cell]{xy}
\UseAllTwocells
```

in the preamble of his or her TEX document.

The issue is in the all-important natural transformation. For instance, the method used by [MR14] is the following:

```
\xymatrix{
A \ar[r]^{\w}_{\;}="a" \ar[d]_{\x}^{\;}="b"&
  B \ar[d]^{\y}\!\!
C \ar[r]_{\x}&
  D \ar@{=>}"a";"b"^{\\alpha} }
```

This involves only the standard `xymatrix` package. It creates two empty labels `\;` at the indicated boxes, and draws a labelled natural transformation arrow \Rightarrow between them. The boxes are placed at the centre of the arrows by means of `-` written before the label name.

Another tactic, by [Gro16], gives:

```
\xymatrix{
A \ar[r]^{\w} \ar[d]_{\x} \drtwocell\omit{\alpha}&
  B \ar[d]^{\y}\!\!
C \ar[r]_{\z}&
  D }
```

$$\begin{array}{ccc}
 A & \xrightarrow{w} & B \\
 x \downarrow & \Downarrow_{\alpha} & \downarrow y \\
 C & \xrightarrow{z} & D
 \end{array}
 \qquad
 \begin{array}{ccc}
 A & \xrightarrow{w} & B \\
 x \downarrow & \Downarrow_{\alpha} & \downarrow y \\
 C & \xrightarrow{z} & D
 \end{array}$$

This uses the `2cell` option of `xymatrix`. It draws an invisible 2-cell between the upper-left and the bottom-right, but leaves the natural transformation associated to it.

This approach is a bit more technically involved, but places the natural transformation in the centre of the commutative diagram – a desirable location. However, it is harder to control the direction of the arrow, and in asymmetric diagrams the resulting picture suffers for it. The dotted arrows below help demonstrate why.¹

```

\begin{array}{c}
\text{\xymatrix{
A\text{\ longer entry} \ar[r]^-{w} \ar[d]_{x} \drtwoocell\omit{\alpha}&
B \ar[d]_{y} \\
C \ar[r]_{z} &
D\text{\readful arrow} }}
\end{array}

```

$$\begin{array}{ccc}
 A \text{ longer entry} & \xrightarrow{w} & B \\
 x \downarrow & \Downarrow_{\alpha} & \downarrow y \\
 C & \xrightarrow{z} & D \text{readful arrow}
 \end{array}
 \qquad
 \begin{array}{ccc}
 A \text{ longer entry} & \xrightarrow{w} & B \\
 x \downarrow & \Downarrow_{\alpha} & \downarrow y \\
 C & \xrightarrow{z} & D \text{readful arrow}
 \end{array}$$

The 2-cell arrow is drawn to be along the perpendicular bisector of the straight arrow between the upper-left and bottom-right. As our square becomes more a rectangle, this direction less and less resembles the direction of the opposing diagonal. In pastings, this becomes awkward:

```

\begin{array}{c}
\text{\xymatrix{
\widetilde{A} \ar[r] \ar[d] \drtwoocell\omit{\gamma}&
x/c \ar[r]^{-\text{\pr}} \ar[d] \drtwoocell\omit{\beta}&
A\text{\ longer entry} \ar[r]^{-w} \ar[d]_{x} \drtwoocell\omit{\alpha}&
B \ar[d]_{y} \\
e \ar[r] & & &
}}
\end{array}

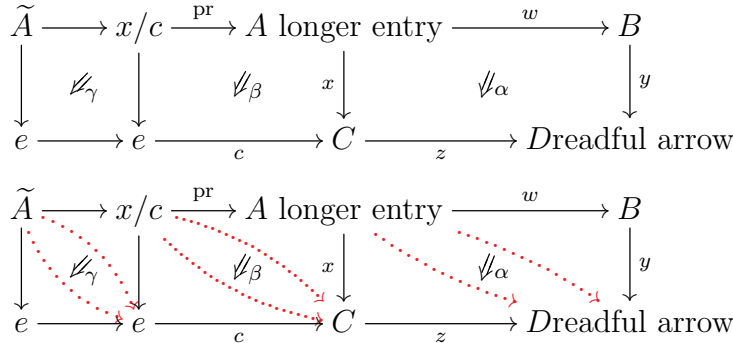

```

¹As a side note: while it is not always necessary to use `-` for centring the labels on the outside square, in the case of asymmetric diagrams it is essential. Here is that diagram without centring the labels:

$$\begin{array}{ccc}
 A \text{ longer entry} & \xrightarrow{w} & B \\
 x \downarrow & \Downarrow_{\alpha} & \downarrow y \\
 C & \xrightarrow{z} & D \text{readful arrow}
 \end{array}$$

I do not prefer this style.

```
e \ar[r]_-c&
C \ar[r]_-z&
D\text{readful arrow} }
```

The arrow seems to change directions slowly. The labelling for the natural transformation seems also to be necessarily below \Rightarrow , and long labels become somewhat awkward:

```
\xymatrix{
A \ar[r]^w \ar[d]_x \drtwocell\omit{\alpha\beta\gamma\delta}&
B \ar[d]_y \\
C \ar[r]_z&
D }
```

This can be solved by adding whitespace within the `\omit{ }` and by lengthening the size of the commutative diagram, and it looks pretty good at the cost of losing the square shape and strictly diagonal arrow:

```
\xymatrix@C=4em{
A \ar[r]^w \ar[d]_x \drtwocell\omit{\quad\;\alpha\beta\gamma\delta}&
B \ar[d]_y \\
C \ar[r]_z&
D }
```

The method I propose attempts to address these problems. First, it puts an arrow pointing in a fixed cardinal direction, even when our commutative diagram is

rectangular. Second, labelling may be done flexibly – it is not as built-in as Groth’s approach, but it allows for longer arrows without the need for tweaking the diagram shape and adding whitespace. It relies on four objects built out of the standard \Rightarrow :

```
\newcommand{\swtrans}
```

```
{\mathbin{\rotatebox[origin=c]{225}{\Rightarrow}}}
```

I call \swarrow the ‘southwest transformation’ (though Australian mathematicians may disagree with this terminology) based on its cardinal direction. A similar command can give one a southeast arrow, etc. We place this in the middle of our standard square as an in-line label of an invisible arrow:

```
\xymatrix{
A \ar[r]^w \ar[d]_x & \ar[d]_y \\
B \ar[d]^y \ar@{}[d1]|\swtrans \\
C \ar[r]_z & D }

```

To label this arrow, we add another invisible arrow shifted slightly above or below, and put our label in-line as well:

```
\xymatrix{
A \ar[r]^w \ar[d]_x & \ar[d]_y \\
B \ar[d]^y \ar@{}[d1]|\swtrans \ar@{}[d1]<-1.0ex>|\alpha \\
C \ar[r]_z & D }

```

The key $<-1.0ex>$ tells the arrow to move right (that is, negative left) by one length of the letter x (roughly). This may need to be tweaked depending on the size of your label and diagram. To repeat the example above,

```
\xymatrix{
A \text{ longer entry} \ar[r]^w \ar[d]_x & \ar[d]_y \\
B \ar[d]^y \ar@{}[d1]|\swtrans \\
\ar@{}[d1]<-1.5ex>|(0.55){\alpha\beta\gamma\delta} \\
C \ar[r]_z & D \text{ elightful arrow} }

```

We have moved our cerulean label arrow by $\langle -1.5ex \rangle$ (0.55). The first means that we have shifted over a little further than in our first example, and the (0.55) means that we move our label from the dead middle of the arrow (which would be (0.5)) a little further towards the tip.

Granted, this is a little more labour-intensive than the previous two methods, but it means you are only changing two numbers. Here is another example, from the definition of a morphism of prederivators:

```

\newcommand{\D}{\mathbb D}
\newcommand{\E}{\mathbb E}
\xymatrix{
\D(K) \ar[r]^{\mathbf{F}_K} \ar[d]_{u^*} & \D(K) & \ar[d]_{u^*} \\
& \E(K) \ar@{\gamma_u^F} @<-1.75ex>[d1] | \{\swtrns\} & \\
\D(J) \ar[r]_{\mathbf{F}_J} & \D(J) & \ar[r]_{\mathbf{F}_J} & \E(J)
}

```

In this case, we shift the arrow by 1.75 x-lengths and do not need to move it along the length of the arrow.
